

## Dynamic and Static analysis of FGM Skew plates with 3D Elasticity based Graded Finite element Modeling

### Abstract

The present article deals with static and dynamic behavior of functionally graded skew plates based on the three-dimensional theory of elasticity. On the basis of the principle of minimum potential energy and the Rayleigh Ritz method, the equations of motion are derived in conjunction with the graded finite element approach. Solution of the resulted system of equations in time domain is carried out via Newmark's time integration method. Calculations are applied for fully clamped boundary condition. In the present paper, two different sets of distributions for material properties are considered. For the static analysis, material properties are considered to vary through the thickness direction according to an exponential law. In the case of dynamic analysis, variations of the volume fractions through the thickness are assumed to obey a power law function. Thus, the effective material properties at each point are determined by the Mori-Tanaka scheme. In case of dynamic analysis, the results are obtained for uniform step loadings. The effects of material gradient index and skew angle on displacement components and stress response are studied. Results of present formulations are verified by available results of a functionally graded rectangular plate for different boundary conditions and also compared with result of a homogenous skew plate by commercial FEM software.

### Keywords

Skew plate; graded finite elements; three-dimensional elasticity; functionally graded materials.

## 1 INTRODUCTION

Functionally graded materials (FGMs) stand as a class of novel composite materials in which mechanical properties vary in one, two or even three specific direction(s). FGMs are especially composite materials constructed from two or more constituent phases with defined composition (Miyamoto et al. 1999; Suresh and Mortensen 1998). Unlike the traditional composites which are piecewise homogeneous mixtures or layered structures, the main feature of structures made of FGMs is

the continuous variation of material properties. Some benefits assigned to FGMs that distinguish them from laminated composites are such as removing the delamination mode of failure, reducing thermal stresses, residual stresses and stress concentration effects. Therefore, the FGMs could be meaningful in practical applications in which the operating conditions are strict, especially in high temperature environments such as in high speed spacecrafts, heat-engine components or rocket heat shields. Skew plates appear in many fields of engineering, such as civil, mechanical, and aerospace engineering. This in turn, it is important to study the static and dynamic behaviors of FGM skew plates to obtain the optimum conditions by choosing the appropriate material distribution profile.

To date, a wide range of research has been carried out on static and dynamic analysis of functionally graded structures which mostly have used the beam, plate and shell theories (Damanpack et al. 2013; Kiani and Eslami 2013; Taj 2013). For thin plates, the classical plate theory (CPT) is used to analyze functionally graded (FG) plate structures. The CPT leads to significant errors in analyzing thick plates because of omitting the influence of shear deformation through the thickness of FG plate structures. As a result, in order to improve the CPT for moderately thick and thick FG plates, some modifications are applied to include the effects of transverse shear deformation. Therefore, the first, third and higher order shear deformation theories and also the 3D elasticity solutions are considered. Among these analyses, 3D elasticity analysis of plates not only provides realistic and accurate results by considering all stress and strain components but also allows further physical insights, which cannot otherwise be estimated by the other two-dimensional or plate theory analyses. Different closed form and approximate solutions have been proposed so far for static and dynamic analysis of skew plates by using the ESL (Equivalent Single-layer) plate theories. Das and et al. (2008) studied Large-amplitude free vibration analysis of simply supported thin isotropic skew plates. The large deformation was imparted statically by subjecting the plate to uniform transverse pressure. Young et al. (2002) presented an investigation into the dynamic stability of skew plates simultaneously under an aerodynamic force in the chordwise direction and a random in-plane force in the spanwise direction. Prabhu et al. (1972) studied the stability of clamped skew plates with the in-plane stresses represented in terms of oblique components. Xiang et al. (1995) formulated the free vibration analysis of skew Mindlin plates with intermediate parallel stiffeners attached in two directions. Akishev et al. (2011) generalized the known analytical solutions of the linearized stability problems for rectangular hinged plates under the combined loading to the similar problems for skew plates, the deformation mechanics of which is described by the equations of the classical theory formed in oblique Cartesian coordinates.

Mechanical behavior of laminated composite skew plates using 3D elasticity and plate theories has been studied rarely. The field equations have generally been solved utilizing the finite element approach in these works. Ng et al. (1985) presented a finite element displacement model for the dynamic and static analysis of clamped and simply supported skew sandwich plates. For static analysis, the sandwich plate was assumed to be uniformly loaded. For the dynamic analysis, results were presented for free flexural vibrations of skew sandwich plates with different plate aspect ratios, angles of skew and core rigidities. Dey et al. (2006) investigated the dynamic stability characteristics of simply supported laminated composite skew plates subjected to a periodic in-plane load using the finite element approach. The principal and second instability regions are identified for different parameters such as skew angle, thickness-to-span ratio, fiber orientation and static in-plane load.

Wu et al. (2006) studied dynamic instability and nonlinear response of rectangular and skew laminated plates subjected to periodic in-plane load. Park et al. (2008) performed a structural dynamic analysis of skew sandwich plates with laminated composite faces based on high-order shear deformation plate theory (HSDT). The effects of skew angles and layup sequences on dynamic response for various parameters were studied using a nonlinear high-order finite element program developed for this study. Lee (2010) studied the finite element dynamic stability analysis of laminated composite skew structures subjected to in-plane pulsating forces based on the higher-order shear deformation theory (HSDT). Qing-qing (1991) discussed the elastic equilibrium problems of anisotropic skew thin plate of variable thickness simply supported on all four sides by nonlinear theories, and used the Navier method to seek an approach to the problem, and to illustrate the solution with examples. Ray et al. (1994) studied nonlinear static and dynamic behaviors of freely supported Rhombic sandwich plates following Banerjee's hypothesis.

Among the FGM plate structures, little attention has been given to FGM skew plates than those of rectangular one. Ganapathi et al. (2006) investigated thermal buckling of a simply supported FG skew plate using first-order shear deformation theory in conjunction with the finite element approach. The effects of aspect and thickness ratios, gradient index, and skew angle on the critical buckling temperature difference are brought out. Upadhyay et al. (2013) studied static and dynamic behavior of FG skew plates. The equations of motion were derived using a higher order shear deformation theory in conjunction with von-Karman's nonlinear kinematics. In case of dynamic analysis, the results were achieved for uniform step, sine, half sine, triangular and exponential type of loadings. The effects of volume fraction index, skew angle and boundary conditions on nonlinear displacement and moment response were presented. Sundararajan et al. (2005) discussed the free vibration characteristics of FGM rectangular and skew plates subjected to thermal environment employing the nonlinear formulation developed based on von Karman's assumptions. The variation of nonlinear frequency ratio with amplitude was highlighted considering various parameters such as gradient index, temperature, thickness and aspect ratios, and skew angle.

According to the above literature review, to date, the ESL theories have been applied to analyze the mechanical response of FGM skew plates. Due to difficulty in obtaining analytical solutions for static and dynamic analysis of FG skew plates, analytical or semi-analytical solutions are available only through a number of problems with simple boundary conditions. Therefore, powerful numerical methods are required to solve the governing equations. Also many researchers have modeled continuous variations of the material properties in the FGM structures by dividing the structure into slices or sub-structures with isotropic material properties. It is evident that this type of modeling leads to approximate rather than accurate global results and unreliable local (such as stress) results. The graded finite element method (GFEM) is a relatively new numerical technique in structural analysis. Kim and Paulino (2002), and Zhang and Paulino (2007) developed a GFEM approach for modeling the nonhomogeneous structures. They compared results of the graded versus conventional homogeneous elements under various loading conditions. In these studies, it was shown that the conventional FE formulations cause a discontinuous stress field in the direction perpendicular to the material property gradation, while the graded elements gave a continuous and smooth variation. Asemi et al. (2012) studied dynamic response of thick short length FGM cylinders under internal impact loading using graded finite element method. Ashrafi et al. (2013) presented a comparative

study between graded finite element and boundary element formulations capable of modeling non-homogeneous behavior of the FGM structures. They showed that using conventional finite element modeling where material properties are constant within an element for dynamic problems leads to considerable discontinuities and inaccuracies. On the other hand by using graded finite element method in which material properties are graded continuously through the elements, the accuracy of the results can be improved without increasing the mesh size.

To the best knowledge of the authors, there are no studies available in the literature on static and dynamic analyses of skew plates based on 3D elasticity and graded finite elements.

In this paper, static and dynamic analysis of functionally graded skew plates based on three dimensional elasticity and graded finite element method is investigated. For the static analysis, material properties are considered to vary through the thickness direction according to an exponential law. For the dynamic analysis, variations of the volume fractions through the thickness are assumed to follow a power law function. In this case, the effective material properties at each point are determined by the Mori–Tanaka scheme. The governing equations are derived based on principle of minimum potential energy and Rayleigh Ritz method. To solve the time dependent equations, Newmark's numerical integration method is employed. The effects of material gradient index and skew angle on static and dynamic behavior of FG skew plates have been investigated.

## 2 THE GOVERNING EQUATIONS

### 2.1 Material gradient and geometry

A functionally graded skew plate as shown in Figure 1 is considered in the present analysis. The Cartesian coordinates vary within the  $(0 < x \leq a+b \operatorname{tg}(\varphi))$ ,  $(0 < y \leq b)$  and  $(0 < z \leq h)$  intervals where  $a$  and  $b/\cos(\varphi)$  are the sides and  $h$  is the thickness of skew plate. The FG skew plate is subjected to a uniform pressure on its upper surface, while its lower surface is free of tractions. Generally, two different sets of distributions for material properties are considered. For the static analysis, FGM is considered in which material properties vary through the thickness of the skew plate according to an exponential law

$$E = E_0 \exp\left(\left(\frac{z}{h}\right)^n\right) \quad (1)$$

where  $n$  is the non- negative material gradient index and  $E_0$  is Young's modulus of the lower surface of the skew plate.

For the dynamic analyses, it is assumed that the FGM skew plate is made of two randomly distributed isotropic phases and the composition of the FGM varies through the thickness direction of the skew plate. The volume fraction of ceramic and metal phases are given by

$$V_c = 1 - \left(\frac{z}{h}\right)^n \quad (2-a)$$

$$V_m = 1 - V_c \quad (2-b)$$

where  $n$  is a non-negative volume fraction index and the subscripts  $c$  and  $m$  stand for the ceramic and the metal phases, respectively.

Mori-Tanaka homogenization method (Mori and Tanaka 1973) is used to determine the effective properties at each point. According to this method, the effective bulk modulus ( $K$ ) and the effective shear modulus ( $G$ ) of the FGM skew plate are defined by

$$\frac{K - K_c}{K_m - K_c} = \frac{V_m}{1 + \frac{(1 - V_m)(K_m - K_c)}{K_c + \frac{4}{3}G_c}} \quad (3)$$

$$\frac{G - G_c}{G_m - G_c} = \frac{V_m}{1 + \frac{(1 - V_m)(G_m - G_c)}{G_c + f_c}} \quad (4)$$

where

$$f_c = \frac{G_c(9K_c + 8G_c)}{6(K_c + 2G_c)} \quad (5)$$

The effective values of the Young's modulus and the Poisson's ratio of the FG skew plate could be written as

$$E = \frac{9KG}{3K + G} \quad (6)$$

$$\nu = \frac{3K - 2G}{2(3K + G)} \quad (7)$$

According to this material distribution, the bottom surface of the FGM skew plate is composed from pure ceramic, the top surface is pure metal, so that different material distributions can be obtained for different values of  $n$ . However, the effective mass density of the FGM skew plate may be determined by the rule of mixtures.

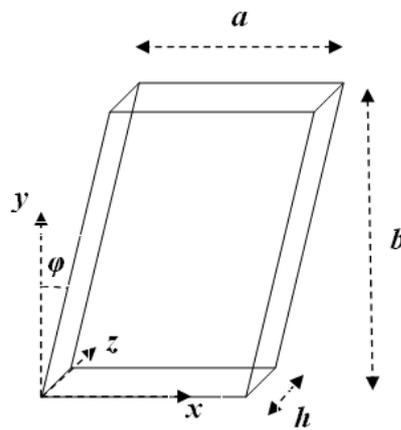

Figure 1 Geometric parameters of the FGM skew plate.

## 2.2 Equations of Motion

The equations of motion in term of stresses in the rectangular Cartesian coordinates for an FGM skew plate can be written as

$$\frac{\partial \sigma_{xx}}{\partial x} + \frac{\partial \sigma_{xy}}{\partial y} + \frac{\partial \sigma_{zx}}{\partial z} = \rho(z) \frac{\partial^2 u}{\partial t^2} \quad (8-a)$$

$$\frac{\partial \sigma_{xy}}{\partial x} + \frac{\partial \sigma_{yy}}{\partial y} + \frac{\partial \sigma_{yz}}{\partial z} = \rho(z) \frac{\partial^2 v}{\partial t^2} \quad (8-b)$$

$$\frac{\partial \sigma_{zx}}{\partial x} + \frac{\partial \sigma_{yz}}{\partial y} + \frac{\partial \sigma_{zz}}{\partial z} = \rho(z) \frac{\partial^2 w}{\partial t^2} \quad (8-c)$$

where  $\rho$  is the mass density which depends on  $z$  coordinate. Also  $u$ ,  $v$  and  $w$  are the displacement components through the  $x$ ,  $y$  and  $z$  directions, respectively and  $\sigma_{ij}$  ( $i, j = x, y, z$ ) are the stress components.

## 2.3 Stress-Strain Relations

The stress-strain relations of the linear elasticity from the Hook's law in term of the modulus of elasticity and Poisson's ratio are (Zienkiewicz 2005)

$$\boldsymbol{\sigma} = \mathbf{D}\boldsymbol{\varepsilon} \quad (9)$$

in which

$$\boldsymbol{\sigma} = \{\sigma_{xx} \quad \sigma_{yy} \quad \sigma_{zz} \quad \sigma_{xy} \quad \sigma_{yz} \quad \sigma_{zx}\}^T \quad (10)$$

$$\boldsymbol{\varepsilon} = \{\varepsilon_{xx} \quad \varepsilon_{yy} \quad \varepsilon_{zz} \quad \varepsilon_{xy} \quad \varepsilon_{yz} \quad \varepsilon_{zx}\}^T \quad (11)$$

$$\mathbf{D} = \frac{E(z)(1-\nu)}{(1+\nu)(1-2\nu)} \begin{pmatrix} 1 & \frac{\nu}{1-\nu} & \frac{\nu}{1-\nu} & 0 & 0 & 0 \\ \frac{\nu}{1-\nu} & 1 & \frac{\nu}{1-\nu} & 0 & 0 & 0 \\ \frac{\nu}{1-\nu} & \frac{\nu}{1-\nu} & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & \frac{1-2\nu}{2(1-\nu)} & 0 & 0 \\ 0 & 0 & 0 & 0 & \frac{1-2\nu}{2(1-\nu)} & 0 \\ 0 & 0 & 0 & 0 & 0 & \frac{1-2\nu}{2(1-\nu)} \end{pmatrix} \quad (12)$$

$$= E(z)\boldsymbol{\Omega}$$

where  $\mathbf{D}$  is the elastic coefficients matrix. It is assumed that the elasticity modulus  $E$  varies in the  $z$  direction while Poisson's ratio  $\nu$  is considered to be constant. The invariant part of matrix  $\mathbf{D}$  is defined as  $\boldsymbol{\Omega}$ .

#### 2.4 Strain-Displacement Relations

For infinitesimal theory of elasticity, the strain- displacement relations, referred to the rectangular Cartesian coordinates system are

$$\begin{aligned} \varepsilon_{xx} &= \frac{\partial u}{\partial x}, \quad \varepsilon_{yy} = \frac{\partial v}{\partial y}, \quad \varepsilon_{zz} = \frac{\partial w}{\partial z}, \quad \varepsilon_{xy} = \frac{1}{2} \left( \frac{\partial u}{\partial y} + \frac{\partial v}{\partial x} \right), \\ \varepsilon_{yz} &= \frac{1}{2} \left( \frac{\partial v}{\partial z} + \frac{\partial w}{\partial y} \right), \quad \varepsilon_{zx} = \frac{1}{2} \left( \frac{\partial w}{\partial x} + \frac{\partial u}{\partial z} \right) \end{aligned} \quad (13)$$

The strain-displacement relations (13) may be written as

$$\boldsymbol{\varepsilon} = \boldsymbol{\Delta} \mathbf{q} \quad (14)$$

where

$$\Delta = \begin{pmatrix} \frac{\partial}{\partial x} & 0 & 0 \\ 0 & \frac{\partial}{\partial y} & 0 \\ 0 & 0 & \frac{\partial}{\partial z} \\ 1/2 \frac{\partial}{\partial y} & 1/2 \frac{\partial}{\partial x} & 0 \\ 0 & 1/2 \frac{\partial}{\partial z} & 1/2 \frac{\partial}{\partial y} \\ 1/2 \frac{\partial}{\partial z} & 0 & 1/2 \frac{\partial}{\partial x} \end{pmatrix} \tag{15}$$

$$\mathbf{q} = \begin{Bmatrix} u \\ v \\ w \end{Bmatrix} \tag{16}$$

For a fully clamped FGM skew plate, the displacement boundary conditions are

$$u, v, w(x, 0, z) = u, v, w(x, b, z) = u, v, w(y = \cot g(\phi)x, z) = u, v, w(y = \cot g(\phi)(x - a), z) = 0 \tag{17}$$

### 3 GRADED FINITE ELEMENT MODELING

The three-dimensional 8-node graded linear brick element in rectangular Cartesian coordinates is considered. In contrast to the conventional solid (brick) elements, material properties are among the nodal degrees of freedom. The finite element approximation follows by discretizing the solution domain into a number of elements and nodal points. The displacement components vector  $\mathbf{q}$  of an arbitrary point of the element may be related to the nodal displacement vector of the element  $\delta^{(e)}$  by using the shape function matrix  $\mathbf{N}$ . The Kantorovich type of approximation is utilized, where the space and time variables are separated as

$$\mathbf{q}(\xi, \eta, \zeta, t) = \mathbf{N}(\xi, \eta, \zeta) \delta^{(e)}(t) \tag{18}$$

where

$$\delta^{(e)} = \{U_1 \ V_1 \ W_1 \ . \ . \ . \ U_8 \ V_8 \ W_8\}^T \tag{19}$$

$$\mathbf{N}(\xi, \eta, \zeta) = \begin{bmatrix} N_1 & 0 & 0 & N_2 & 0 & 0 & N_3 & 0 & 0 & N_4 & 0 & 0 & N_5 & 0 & 0 & N_6 & 0 & 0 & N_7 & 0 & 0 & N_8 & 0 & 0 \\ 0 & N_1 & 0 & 0 & N_2 & 0 & 0 & N_3 & 0 & 0 & N_4 & 0 & 0 & N_5 & 0 & 0 & N_6 & 0 & 0 & N_7 & 0 & 0 & N_8 & 0 \\ 0 & 0 & N_1 & 0 & 0 & N_2 & 0 & 0 & N_3 & 0 & 0 & N_4 & 0 & 0 & N_5 & 0 & 0 & N_6 & 0 & 0 & N_7 & 0 & 0 & N_8 \end{bmatrix} \quad (20)$$

and the natural coordinates  $\xi$ ,  $\eta$ , and  $\zeta$  are along the coordinate axes  $x$ ,  $y$ , and  $z$ , respectively. The components of the shape matrix may be expressed in terms of the natural coordinates as (Zienkiewicz 2005):

$$N_i(\xi, \eta, \zeta) = \frac{1}{8}(1 + \xi_i \xi)(1 + \eta_i \eta)(1 + \zeta_i \zeta) \quad (21)$$

where  $(-1 \leq \xi \leq 1)$ ,  $(-1 \leq \eta \leq 1)$  and  $(-1 \leq \zeta \leq 1)$ .

The details of transformations between Cartesian coordinate system and natural coordinates could be found in finite element textbooks, see (Zienkiewicz, 2005).

To model the problem, the Graded Finite Element Method (GFEM) is used. In this method, in addition to the displacement field, the functionally graded material properties of the skew plate may also be interpolated based on their nodal values. Using the graded elements cause continuous gradation of material properties at the element level and gives more accurate results than dividing the solution domain into homogenous elements, especially to model the dynamic problems. In this regard, shape functions similar to those of the displacement field may be applied:

$$\begin{aligned} E(\zeta) &= \sum_{i=1}^8 E_i N_i(\xi, \eta, \zeta) = \hat{\mathbf{N}} \mathbf{\Xi} \\ \rho(\zeta) &= \sum_{i=1}^8 \rho_i N_i(\xi, \eta, \zeta) = \hat{\mathbf{N}} \mathbf{\Re} \end{aligned} \quad (22)$$

where  $E_i$  and  $\rho_i$  are the modulus of elasticity and mass density values corresponding to node  $i$  (Figure 2), and  $\mathbf{\Xi}$  and  $\mathbf{\Re}$  are vectors of the nodal elasticity moduli and mass densities, respectively as

$$\hat{\mathbf{N}} = \left\langle N_1 \quad N_2 \quad \dots \quad N_8 \right\rangle, \quad \mathbf{\Xi} = \left\langle E_1 \quad E_2 \quad \dots \quad E_8 \right\rangle^T, \quad \mathbf{\Re} = \left\langle \rho_1 \quad \rho_2 \quad \dots \quad \rho_8 \right\rangle^T \quad (23)$$

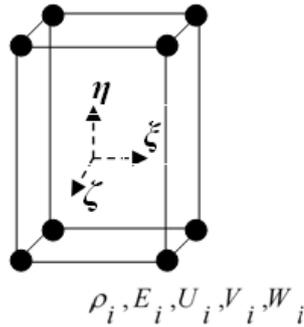

Figure 2 Nodal degrees of freedom of the *i*th node of the adopted graded three-dimensional element

Therefore, Eq. (12) may be rewritten as:

$$\mathbf{D} = \Omega(\widehat{\mathbf{N}}\Xi) \tag{24}$$

Substituting (18) into (14) gives the strain matrix of the element (*e*)

$$\boldsymbol{\varepsilon}^{(e)} = \Delta\mathbf{N}\boldsymbol{\delta}^{(e)} = \mathbf{B}\boldsymbol{\delta}^{(e)} \tag{25}$$

The governing equations of the FE model may be obtained based on principle of minimum potential energy and Rayleigh Ritz method. The total potential energy of the skew plate may be expressed as

$$\begin{aligned} \Pi^{(e)} &= \frac{1}{2} \int_{V^{(e)}} (\boldsymbol{\varepsilon}^{(e)})^T \boldsymbol{\sigma}^{(e)} dV - \int_{A^{(e)}} (\mathbf{q})^T \mathbf{p} dA + \int_{V^{(e)}} \rho(\mathbf{q})^T \ddot{\mathbf{q}}^{(e)} dV \\ &= \frac{1}{2} \int_{V^{(e)}} (\boldsymbol{\delta}^{(e)})^T \mathbf{B}^T \Omega(\widehat{\mathbf{N}}\Xi) \mathbf{B} \boldsymbol{\delta}^{(e)} dV - \int_{A^{(e)}} (\boldsymbol{\delta}^{(e)})^T \mathbf{N}^T \mathbf{p} dA \\ &\quad + \int_{V^{(e)}} (\boldsymbol{\delta}^{(e)})^T \mathbf{N}^T (\widehat{\mathbf{N}}\mathfrak{K}) \mathbf{N} \ddot{\boldsymbol{\delta}}^{(e)} dV \end{aligned} \tag{26}$$

where  $V^{(e)}$  and  $A$  are volume and area of the element;  $\mathbf{p}$  is the traction vector and the last term of Eq. (26) is inertial loads work.

Therefore, the principle of minimum total potential energy leads to the following equation:

$$\begin{aligned} \frac{\partial \Pi^{(e)}}{\partial (\boldsymbol{\delta}^{(e)})^T} &= 0 \\ \Rightarrow \left[ \int_{V^{(e)}} \mathbf{N}^T (\widehat{\mathbf{N}}\mathfrak{K}) \mathbf{N} dV \right] \ddot{\boldsymbol{\delta}}^{(e)} + \left[ \int_{V^{(e)}} \mathbf{B}^T \Omega(\widehat{\mathbf{N}}\Xi) \mathbf{B} dV \right] \boldsymbol{\delta}^{(e)} &= \int_{A^{(e)}} \mathbf{N}^T \mathbf{p} dA \end{aligned} \tag{27}$$

or in a compact form:

$$\mathbf{M}^{(e)} \ddot{\boldsymbol{\delta}}^{(e)} + \mathbf{K}^{(e)} \boldsymbol{\delta}^{(e)} = \mathbf{F}^{(e)} \quad (28)$$

where

$$\mathbf{K}^{(e)} = \int_{V^{(e)}} \mathbf{B}^T \boldsymbol{\Omega} (\widehat{\mathbf{N}} \boldsymbol{\Xi}) \mathbf{B} dV \quad (29)$$

$$\mathbf{M}^{(e)} = \int_{V^{(e)}} \mathbf{N}^T (\widehat{\mathbf{N}} \boldsymbol{\Re}) \mathbf{N} dV \quad (30)$$

$$\mathbf{F}^{(e)} = \int_{A^{(e)}} \mathbf{N}^T \mathbf{p} dA \quad (31)$$

and

$$\mathbf{p} = \begin{Bmatrix} 0 \\ 0 \\ p_z \end{Bmatrix} \quad (32)$$

Since the skew plate is subjected to a uniform pressure at its upper surface, components of the traction vector are equal to zero in the  $x$  and  $y$  directions. Integrals of the mass and stiffness matrices are calculated numerically using 8-point Gaussian points and Gauss-Legendre technique (Zienkiewicz 2005).

By assembling the element matrices, the governing finite element equations of motion of the FGM skew plate will have the following form

$$\mathbf{M} \ddot{\boldsymbol{\delta}} + \mathbf{K} \boldsymbol{\delta} = \mathbf{F} \quad (33)$$

Various numerical methods can be used to solve equation (33) in the space and time domains. To solve the equations of motion, the Newmark's numerical integration method (Zienkiewicz 2005) is applied. Newmark integration parameters are chosen as:  $\gamma = \frac{1}{2}$  and  $\beta = \frac{1}{4}$ , which lead to a constant average acceleration. This choice of parameters corresponds to the trapezoidal rule which is unconditionally stable in linear analyses. Moreover, the time step is taken as  $2e-6$  (s). This value is small enough to ensure convergence, and truly exhibit the vibrational characteristics and the behavior of the system. In other words, the system will not exhibit its vibration behavior for larger time increments. Thus, it is required enough short time period dynamical excitations to motivate and excite higher natural frequencies and mode shapes of the structure. A criteria to select proper value for time increment is (Bathe and Wilson, 1976)

$$\Delta t \leq \Delta t_{cr} = T_n / \pi \quad (34)$$

where  $T_n$  is the period of lowest natural frequency of the structure.

For static analysis, Eq. (33) is reduced to

$$\mathbf{K}\delta = \mathbf{F} \tag{35}$$

### 4 RESULTS AND DISCUSSION

This section includes several subsections, in which each is appropriated to a specific purpose. In this regard, verification of the present results, effects of material gradient index and skew angle are discussed in detail.

#### 4.1 Verification of the results

Since researches on the subject of FGM skew plates under static and dynamic loadings are almost rare in the open literature, the present solution is verified using data of the FGM rectangular plate at the same conditions as were previously presented by (Rezaei Mojdehi et al. 2011). The effective material properties are determined by the Mori-Tanaka scheme and parameters are defined as  $n = 1$ ,  $a = b$ ,  $\frac{h}{a} = 0.2$ ,  $E_m = 70 \text{ GPa}$ ,  $E_c = 200 \text{ GPa}$ ,  $\varphi = 0^\circ$ ,  $P = 1 \text{ Pa}$  and  $\nu = 0.3$ . The non-dimensional transverse displacement through the thickness for the FGM plate with different boundary conditions are marked as: 1-Fully clamped, 2- Two simply supported and two clamped edges, 3-Fully simply supported and 4- Two simply supported and two free edges. Also, the present results are compared with those reported by published data. Figure 3 shows good agreement between the results.

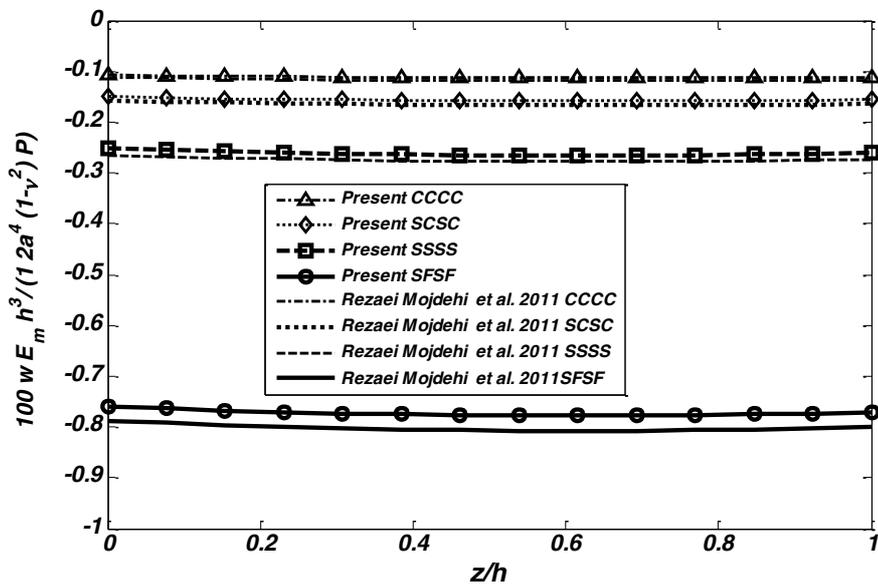

Figure 3 Non-dimensional transverse displacement through the thickness at  $x = y = \frac{a}{2}$  compared with those developed by Rezaei Mojdehi et al. (2011)

Furthermore, static analysis of a thick homogenous skew plate is also considered. The skew plate is fully clamped and subjected to a uniform pressure at its upper surface. The geometry and material properties of the skew plate are considered as:  $h=0.1$  m,  $a=0.5$  m,  $b=1$  m,  $\varphi=30^\circ$ ,  $E=E_0=70$  Gpa,  $\nu=0.3$ ,  $P=20$  MPa at top surface

The through-the-thickness lateral deflection of central section of skew plate is obtained and compared with result of commercial FEM software ANSYS Workbench, as shown in Figure 4. Comparison between the results shows good agreement.

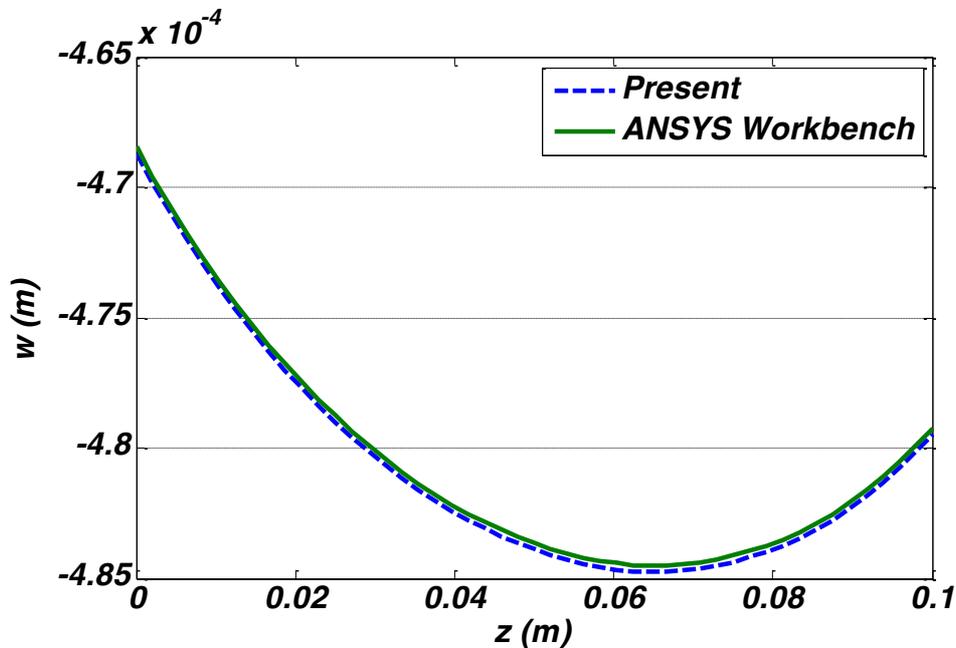

Figure 4 A comparison between through-the-thickness distributions of the lateral deflection of the central section of the homogeneous skew plate predicted by present results and ANSYS Workbench software

## 4.2 Static analysis

An FGM skew plate stands with sides  $a=0.5$  m,  $b=1$  m and thickness  $h = 0.1$  m. The material properties vary through thickness direction according to an exponential material gradation provided in Eq. (1) with  $E_0 = 70$  (GPa). The plate is subjected to a uniform pressure loading  $P$  in the  $z$ -direction on its top surface, while fully clamped edges is considered. The static pressure is taken as  $P = 20$  MPa. Number of graded elements through the  $x$ ,  $y$  and  $z$  directions are obtained  $12*24*7$ , according to a mesh sensitivity study to obtain an accurate solution with a mesh that is sufficiently dense and not overly demanding of computing resources. Table 1 shows the convergence study of the normal stress  $\sigma_{xx}$  of the center point of the fully clamped FGM skew plate for  $\varphi=20^\circ$  and  $n=1$ . This table shows that the maximum discrepancy for graded elements is about 1.95 % while this value for homogenous type is about 7.23 %. It can be deduced that for the homogenous elements, the results based on mesh convergence study need much more elements in comparison with graded elements one.

Table 1 Mesh convergence study of the normal stress  $\sigma_{xx}$  of the center point of the fully clamped FGM skew plate for  $\varphi=20^\circ$  and  $n=1$

Number of graded elements	12*24*4	12*24*5	12*24*6	12*24*7
$\sigma_{xx}$ (MPa)	16.14 (1.95 %)	15.98 (0.948 %)	15.9 (0.44 %)	15.83
Number of homogenous elements	12*24*4	12*24*5	12*24*6	12*24*7

Through-the-thickness distribution of the transverse deflection of the central section ( $x = \frac{a}{2} + \frac{b}{2} \tan(\varphi), y = \frac{b}{2}$ ) of the FGM skew plate is shown in Fig. 5 for different material gradient index  $n = 1, 3$  and  $5$  (the skew angle kept fixed  $\varphi=20^\circ$ ). As it may be deduced that deflections increases as  $n$  increases from  $n=1$  to  $5$ . This is because that, by increasing the material gradient index, the stiffness of the skew plate is decreased. furthermore, it may be concluded that no matter to what value the material property index, the magnitude of transverse deflection in bottom surface are lower in comparison with those developed in the top one. This behavior is because that the FGM plate is analyzed by three-dimensional theory of elasticity, therefore, the transverse compressibility of the plate is considered.

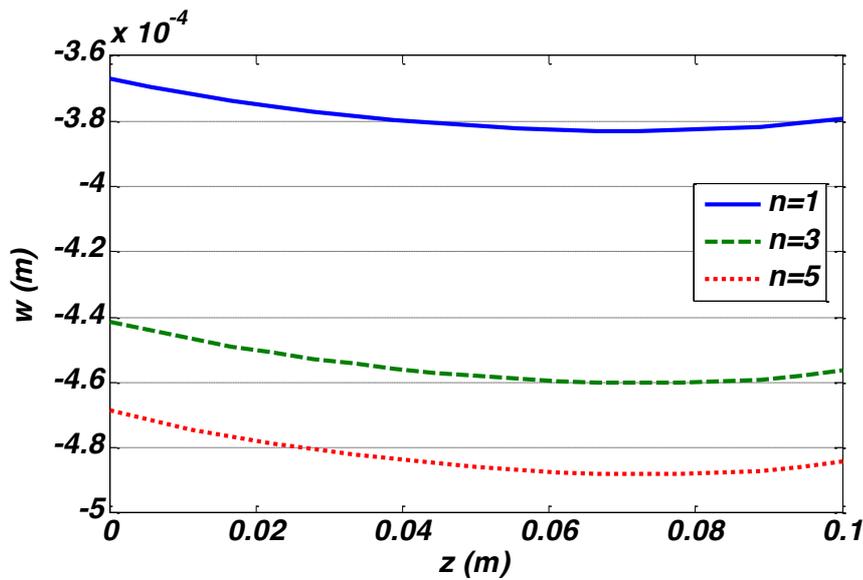

Figure 5 Through-the-thickness distribution of the transverse deflection of the central section of the skew plate for different grading exponent and  $\varphi = 20^\circ$

Figs. 6 and 7 illustrate through-the-thickness distribution of the in-plane normal and shear stresses of the central section of the FGM skew plate for different material gradient index  $n = 1, 3$  and  $5$ , respectively ( $\varphi=20^\circ$ ). According to latter discussion about lateral deflection, by increasing the material gradient index and consequently reducing the stiffness of plate the curvature of the plate increases. Therefore, as results shown in Figs.6 and 7, increasing the material property in-

dex leads to increase the in- plane normal and shear stress components,  $(\sigma_{xx}, \sigma_{xy})$  in the top and bottom surfaces. However, the resulting behavior is different through the thickness. Indeed, that is probably affected by the material nonlinearity of the FGM plate. Also, it may be deduced from results, the magnitude of in- plane normal and shear stress components in bottom surface are lower in comparison with those developed in top one regardless of what value material gradient index. This behavior is may be due to the curvature of the bottom surface is lower than the top one.

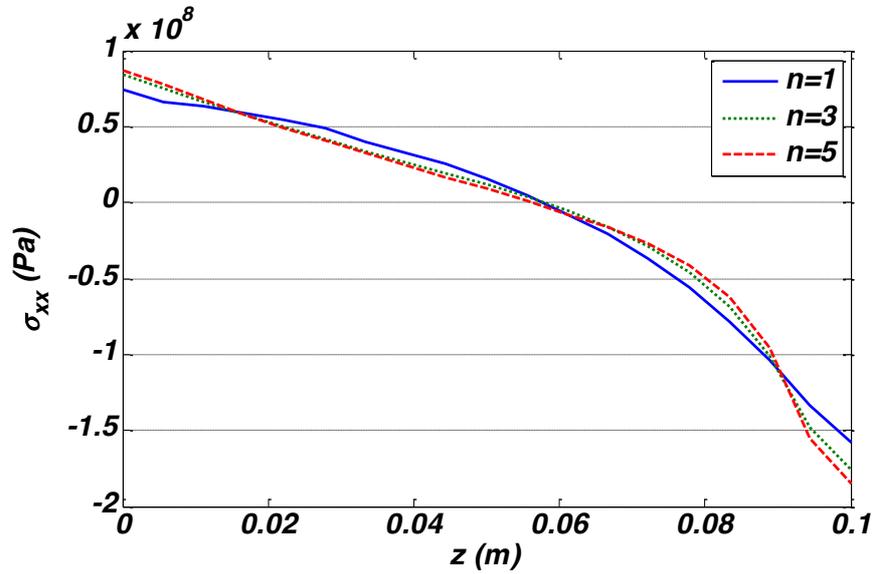

Figure 6 Through-the-thickness distribution of the normal stress  $\sigma_{xx}$  of the central section of the skew plate for different grading exponent and  $\varphi = 20^\circ$

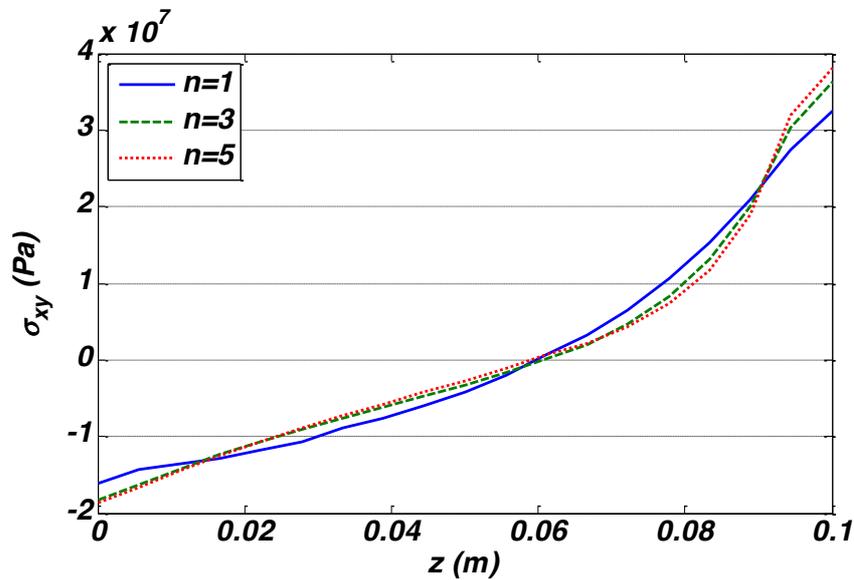

Figure 7 Through-the-thickness distribution of the shear stress  $\sigma_{xy}$  of the central section of the skew plate for different grading exponent and  $\varphi = 20^\circ$

Effects of the skew angle on through thickness distribution of transverse deflection and in- plane normal and shear stress components of the central section of the FGM skew plate are depicted in Figs. 8 to 10 ( $n=3$ ). It is observed that with increasing skew angle, the transverse deflection decreases due to stiffening the plate involved with increasing the skew angle. On the other hand, with increasing skew angle there is an increase of in- plane shear stress component. It shows that increasing the skew angle is coupled to curvature growth. Furthermore, it is noticed that the effect of skew angle on in- plane shear stress is more significantly in comparison with normal stress ( $\sigma_{yy}$ ).

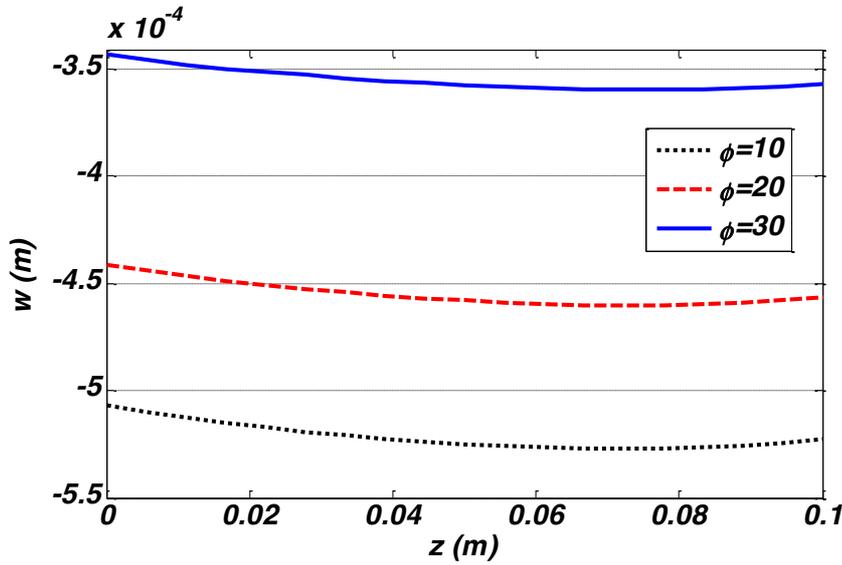

Figure 8 Through-the-thickness distribution of the transverse deflection of the central section of the skew plate for different skew angle and  $n=3$

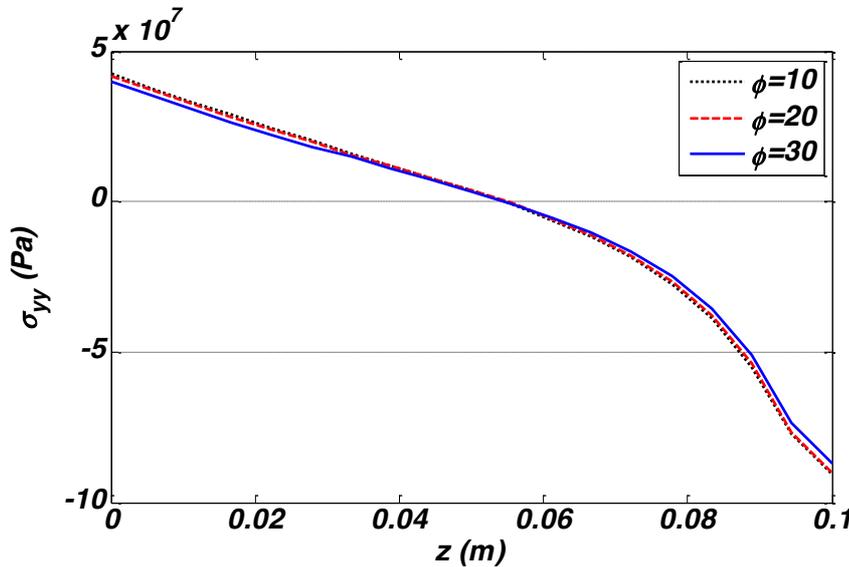

Figure 9 Through-the-thickness distribution of the normal stress  $\sigma_{yy}$  of the central section of the skew plate for different skew angle and  $n=3$

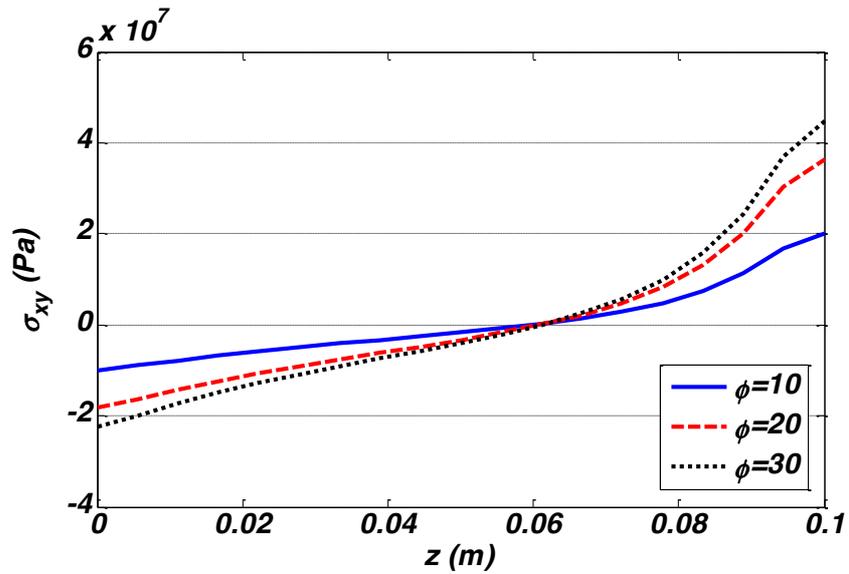

Figure 10 Through-the-thickness distribution of the shear stress  $\sigma_{xy}$  of the central section of the skew plate for different skew angle and  $n=3$

Distributions of the transverse deflection and the displacement component ( $u$ ) of the mid-plane of the FGM skew plate are depicted along the horizontal axis ( $y=b/2, z=h/2$ ) in Figs. 11 and 12 for different gradation exponents ( $\phi = 20^\circ$ ). As it may be noticed from results, both of displacement components show identical behavior for  $n=1$  to 3. But, displacement component  $u$  is decreased for  $n=3$  to 5. This is may be due to nonlinear behavior of the FGMs.

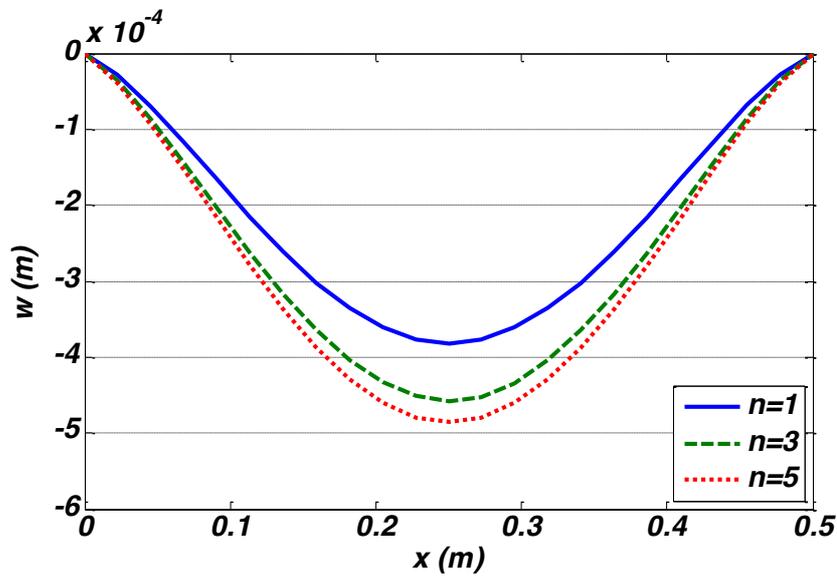

Figure 11 Distribution of transverse displacement at  $y = \frac{b}{2}, z = \frac{h}{2}$  for different grading exponent and  $\phi = 20^\circ$

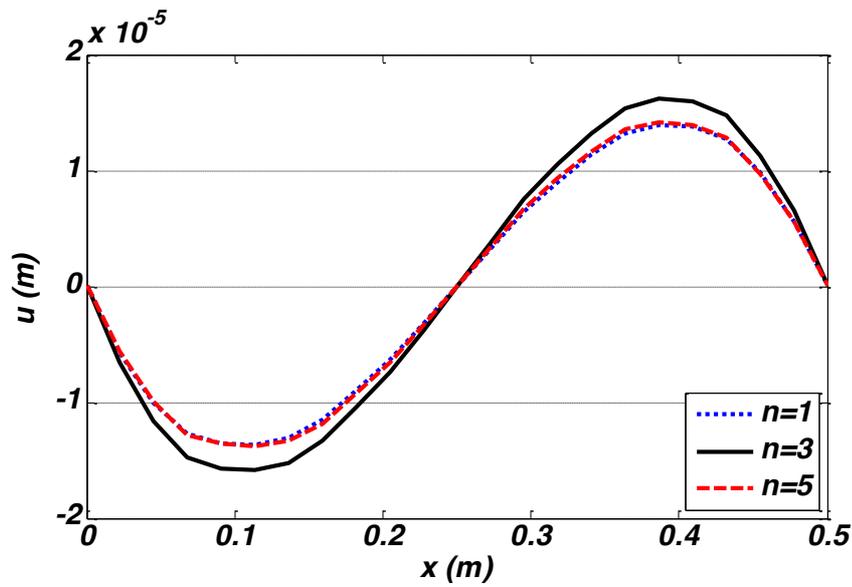

Figure 12 Distribution of displacement component  $u$  at  $y = \frac{b}{2}, z = \frac{h}{2}$  for different grading exponent and  $\varphi = 20^\circ$

Variations of the in- plane normal stress and transverse shear stress components of the mid-plane of the skew plate are shown along the horizontal axis ( $y=b/2, z=h/2$ ) in Figs. 13 and 14 for different gradation exponents ( $\varphi = 20^\circ$ ). Results illustrated in Fig. 13 reveal that distribution of the stress component  $\sigma_{yy}$  changes significantly depends on value of gradation exponent  $n$ . However, this effect is not seen considerably in transverse shear stress ( $\sigma_{yz}$ ), see Fig. 14.

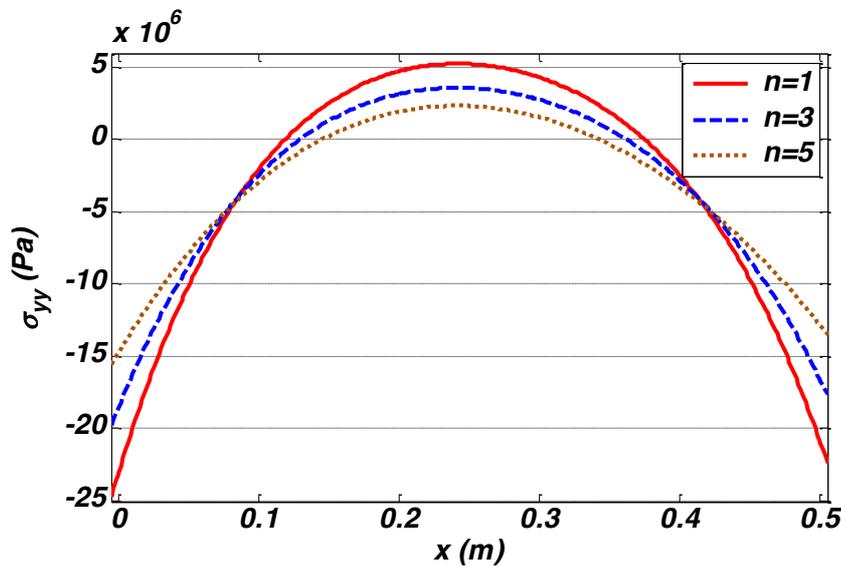

Figure 13 Distribution of normal stress  $\sigma_{yy}$  at  $y = \frac{b}{2}, z = \frac{h}{2}$  for different grading exponent and  $\varphi = 20^\circ$

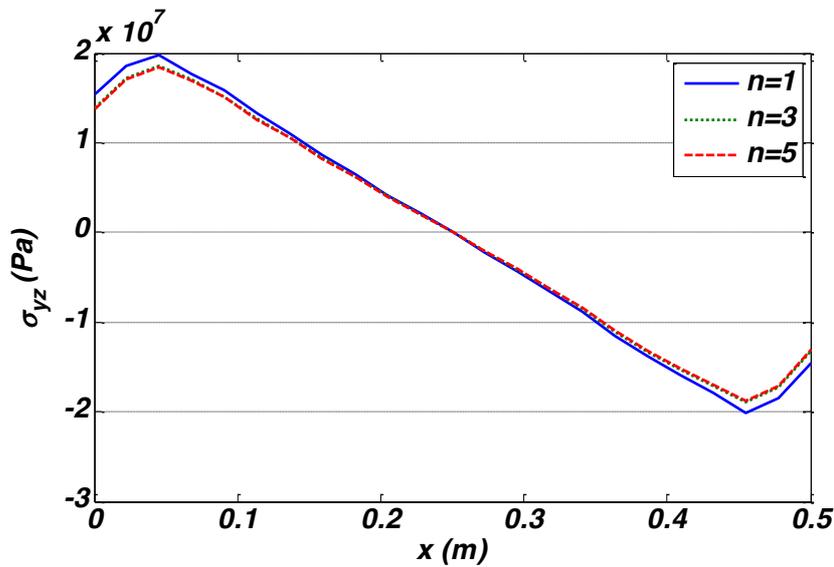

Figure 14 Distribution of shear stress  $\sigma_{yz}$  at  $y = \frac{b}{2}, z = \frac{h}{2}$  for different grading exponent and  $\varphi = 20^\circ$

Distribution of the of the transverse deflection and the displacement component ( $u$ ) of the mid-plane of the skew plate are shown along the horizontal axis ( $y=b/2, z=h/2$ ) in Figs. 15 and 16 for various skew angles ( $n = 3$ ). The results indicate increasing the skew angle causes decrease both displacement components. As it has been discussed formerly with increase of skew angle, the displacement components decrease due to the stiffening of the plate involved with higher skew angle. According to the obtaining results, with increase of skew angle there is a decrease of in-plane normal stress component, see Fig.17. It could be concluded that unlike the effects of skew angle on distribution of stress through the thickness, increase in the skew angle leads to decreasing the in- plane stress component due to probably the plate tightened with higher skew angle. Finally, it can be seen from results of the stress components, both the through-thickness and longitudinal distributions of the stress components have continuous variations due to using graded elements.

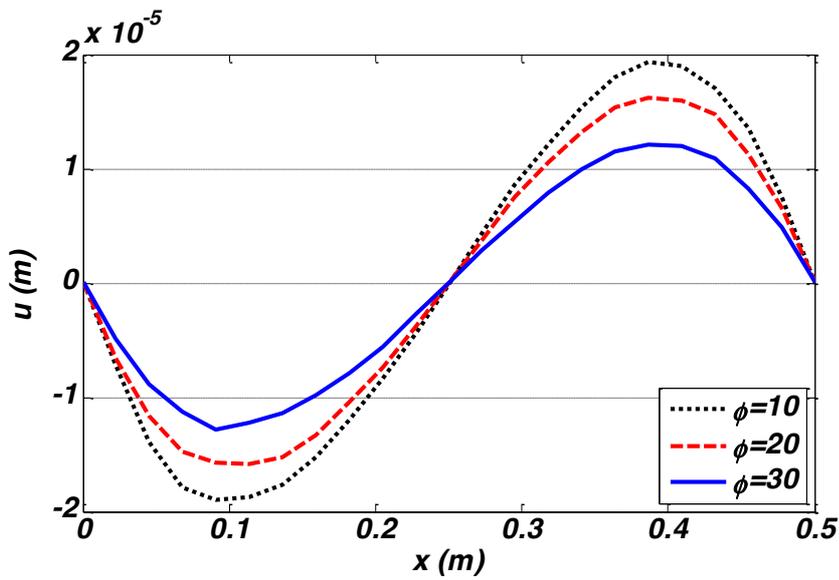

Figure 16 Distribution of displacement component  $u$  at  $y = \frac{b}{2}, z = \frac{h}{2}$  for different skew angle and grading exponent  $n=3$

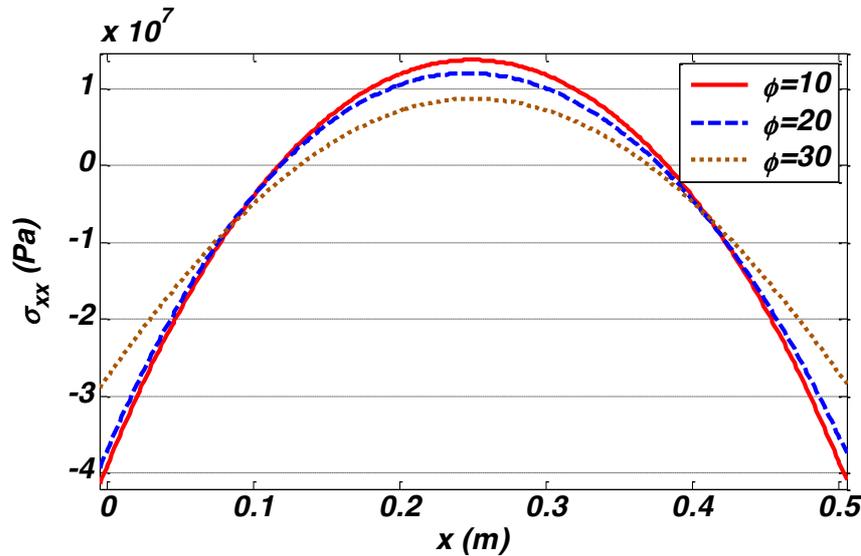

Figure 17 Distribution of normal stress  $\sigma_{xx}$  at  $y = \frac{b}{2}, z = \frac{h}{2}$  for different skew angle and grading exponent  $n=3$

### 4.3 Dynamic Analysis

The skew FGM plate of the previous section is considered once again. As indicated before, the functionally graded plate consists of a mixture of ceramic at the bottom and metal at the top having the thickness ‘ $h$ ’ considered in the present study. In order to obtain the effective properties of FGM plate the Mori–Tanaka homogenization method is utilized. The material properties of the constituent materials are assumed to be  $E_c=380$  (GPa),  $\rho_c=3800$  (kg/m<sup>3</sup>) and  $E_m=70$  (GPa),  $\rho_m=2707$  (kg/m<sup>3</sup>).

The numerical results presented in this section deal with the dynamic response of a fully clamped skew plate subjected to following uniformly distributed dynamic load at its top surface.

$$p(t) = \begin{cases} p_0 t & t \leq 0.005 \text{ (s)} \\ 0 & t > 0.005 \text{ (s)} \end{cases}$$

where  $p_0$  is supposed as  $4 \text{ GPa/s}$  during the analyses. The plate is unloaded in  $t=0.005$  (s). As it may be known, after the unloading, a transient vibration which is affected by the wave propagation, reflection and interference would occur. The influence of various material properties, exponents and skew angles on dynamic response is presented and discussed in the subsequent paragraphs.

Fig. 18 indicates time history of the transverse deflection of the center point ( $x = \frac{a}{2} + \frac{b}{2} \tan(\varphi), y = \frac{b}{2}, z=h/2$ ) of the skew plate after the unloading for different gradation exponents ( $\varphi = 10^\circ$ ). The result shows that by increasing the gradation exponent, the volume fraction of the ceramic phase increases and subsequently, the amplitude of the vibration decreases. Furthermore, the vibration frequency is increased with the material property exponent. It is because the plate is stiffened due to increasing the volume fraction index of the ceramic phase.

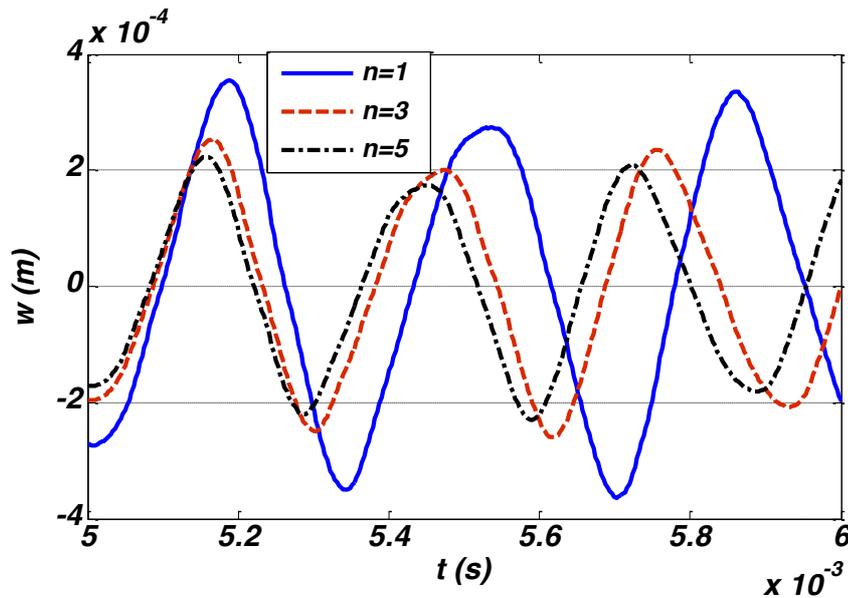

Figure 18 Time history of transverse deflection at  $x = \frac{a}{2} + \frac{b}{2} \tan(\varphi)$ ,  $y = \frac{b}{2}$ ,  $z = \frac{h}{2}$  for skew plate with  $\varphi = 10^\circ$  and for different grading exponent

Figs. 19 to 22 show the time histories of the stress components  $\sigma_{xx}$ ,  $\sigma_{xy}$ ,  $\sigma_{yz}$  and  $\sigma_{zz}$  of the skew plate center point ( $x = \frac{a}{2} + \frac{b}{2} \tan(\varphi)$ ,  $y = \frac{b}{2}$ ,  $z = \frac{h}{2}$ ) for different gradation exponents and  $\varphi = 10^\circ$ , respectively. Results reveal that propagation of the stress waves following the unloading is affected by the volume fraction index significantly. However, this influence is more considerable in time histories of transverse stress components. This is because the assumed FGM plate material properties vary only through the thickness. As a result, the behavior of transverse stresses is more correlated to magnitude of gradation exponent in comparison with that dependence of in-plane stresses. As increasing volume fraction index causes increasing the plate stiffness, it may be concluded from the obtained results for transverse stress components, stress wave propagation is more rapid in the higher index case, see Figs.21 and 22.

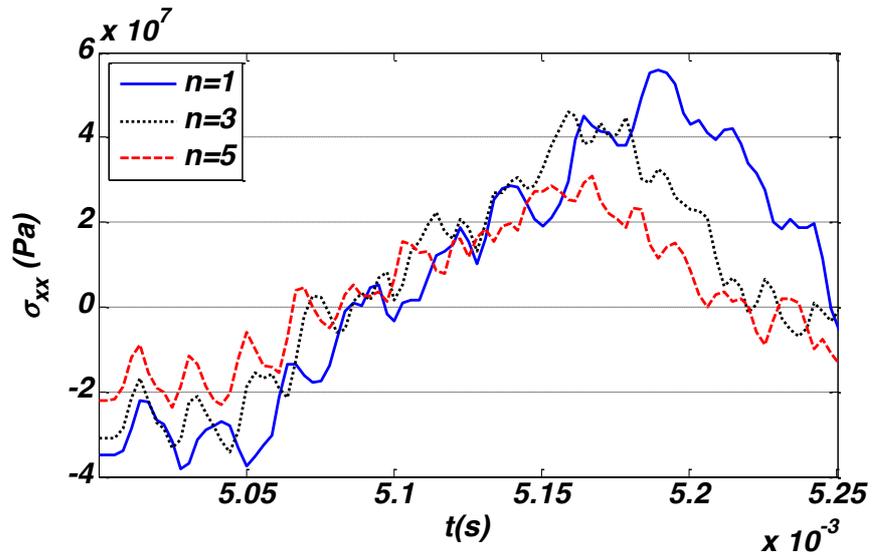

Figure 19 Time history of normal stress  $\sigma_{xx}$  of the center point of the skew plate for different gradation exponents and  $\varphi = 10^\circ$

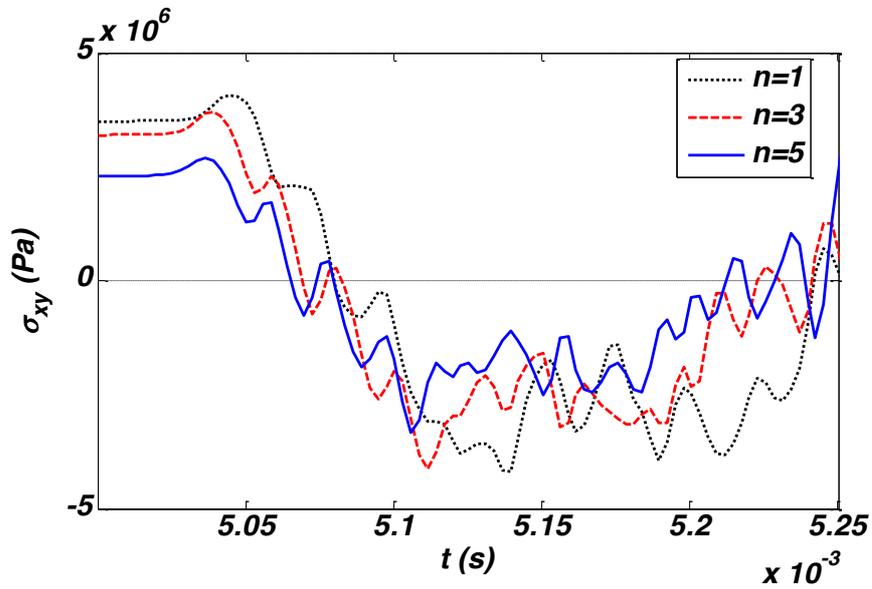

Figure 20 Time history of shear stress  $\sigma_{xy}$  of the center point of the skew plate for different gradation exponents and  $\varphi = 10^\circ$

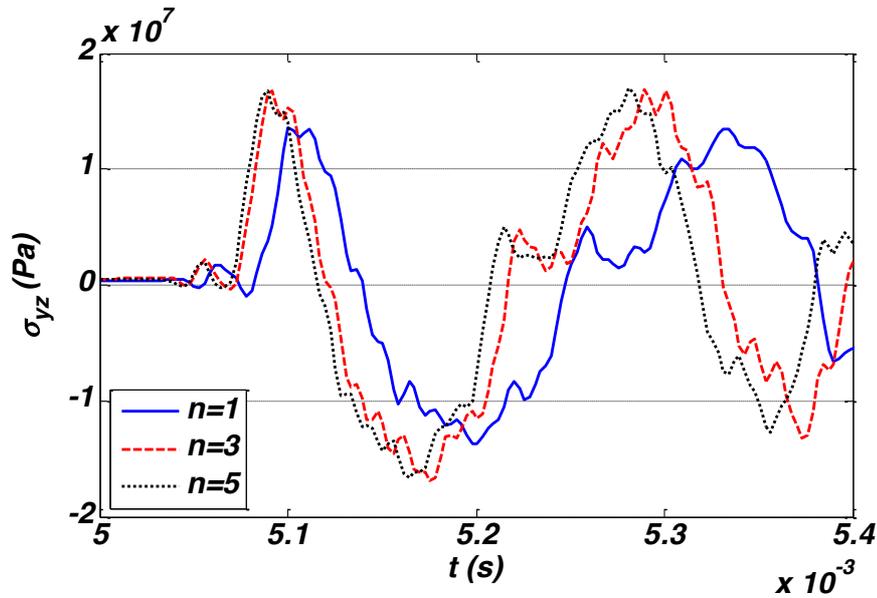

Figure 21 Time history of shear stress  $\sigma_{yz}$  of the center point of the skew plate for different gradation exponents and  $\varphi = 10^\circ$

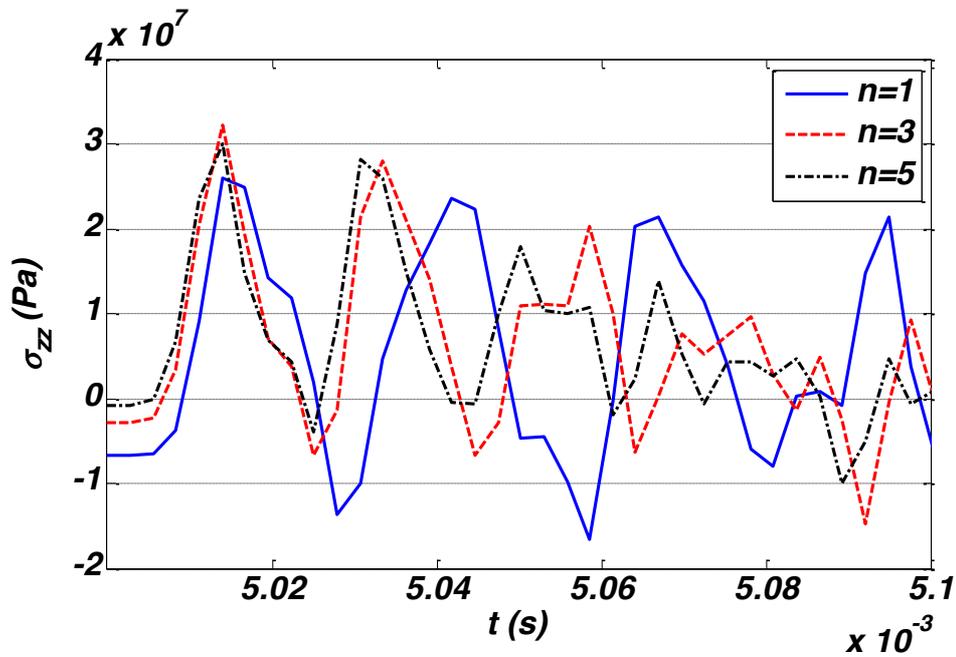

Figure 22 Time history of normal stress  $\sigma_{zz}$  of the center point of the skew plate for different gradation exponents and  $\varphi = 10^\circ$

The effect of skew angle on time history of transverse deflection for the center point of the skew plate is shown in Fig.23. It could be observed that by increasing skew angle, amplitude decrease and vibration frequency is increased. It is because that the plate is stiffened due to higher skew angle.

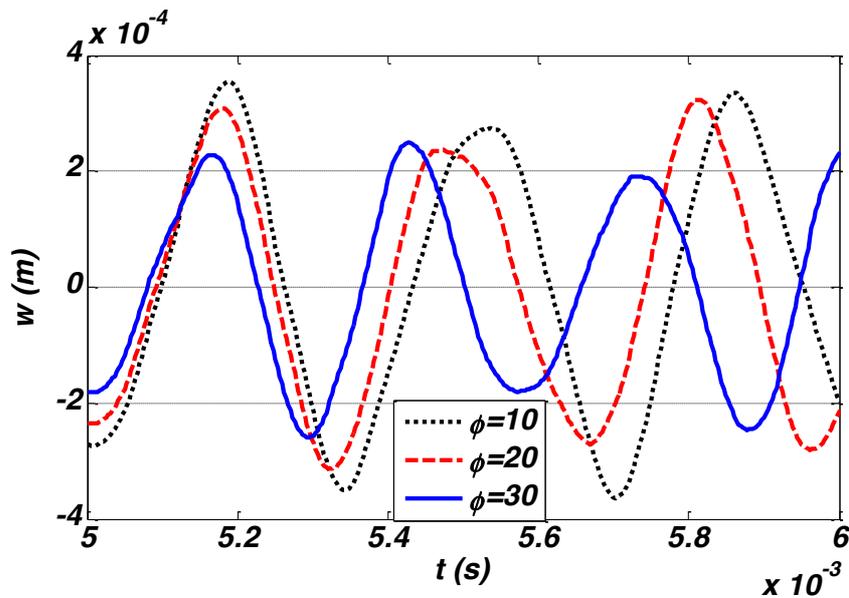

Figure 23 Time history of transverse displacement of the center point of the skew plate for different skew angle and grading exponent  $n=1$

The influence of various skew angles on time histories of stress components  $\sigma_{xx}$ ,  $\sigma_{xy}$ ,  $\sigma_{zz}$  and  $\sigma_{zx}$ , is illustrated in Figs. 24 to 27. Results reveal that propagation of the stress waves subsequent the unloading is significantly affected by the skew angle. The skew plate mid-plane transverse deflection for  $n=1$  and  $\varphi = 30^\circ$  at specified times after the unloading are shown in Figs. 28. These figures show the vibration mode shapes of the FGM skew plate after the unloading.

Results denote that the propagation of stress waves after the unloading is strongly affected by the grading exponent and skew angle. The obtained results show that the use of a graded element has several advantages over the use of conventional elements in the dynamic and wave propagation analyses. In conventional FE methods, continuous variations of the material properties are approximated by discrete and homogenous elements. Therefore, adjacent elements may have quite different isotropic material properties and severe discontinuity of the material properties is observed in boundaries of these homogenous elements. As a result, creation of artificial wave reflections causes cumulative effects on magnitude and speed of the stress waves propagation. Therefore, by utilizing the graded elements in which the material properties vary continuously, enhanced accuracy may be achieved without updating the mesh size.

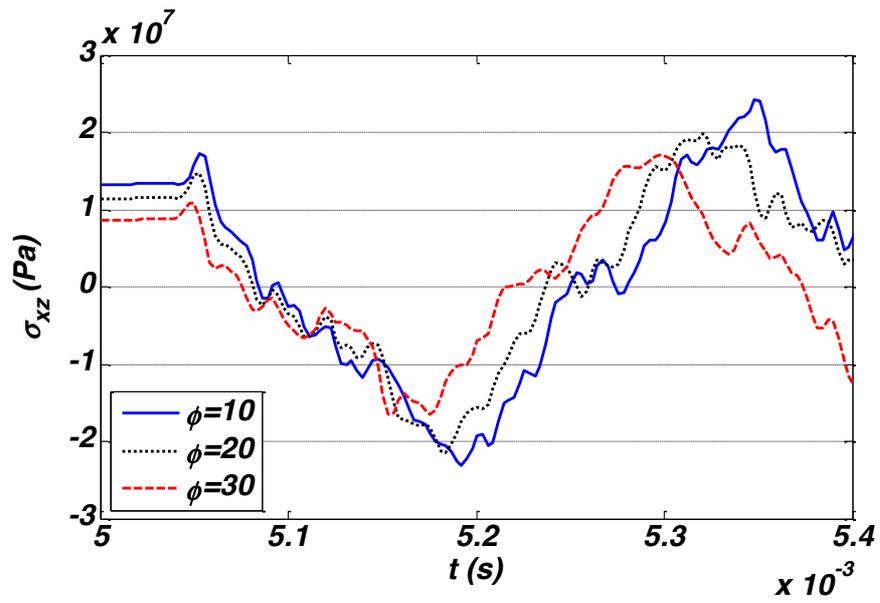

Figure 27 Time history of shear stress  $\sigma_{xz}$  of the center point of the skew plate for different skew angle and grading exponent  $n=1$

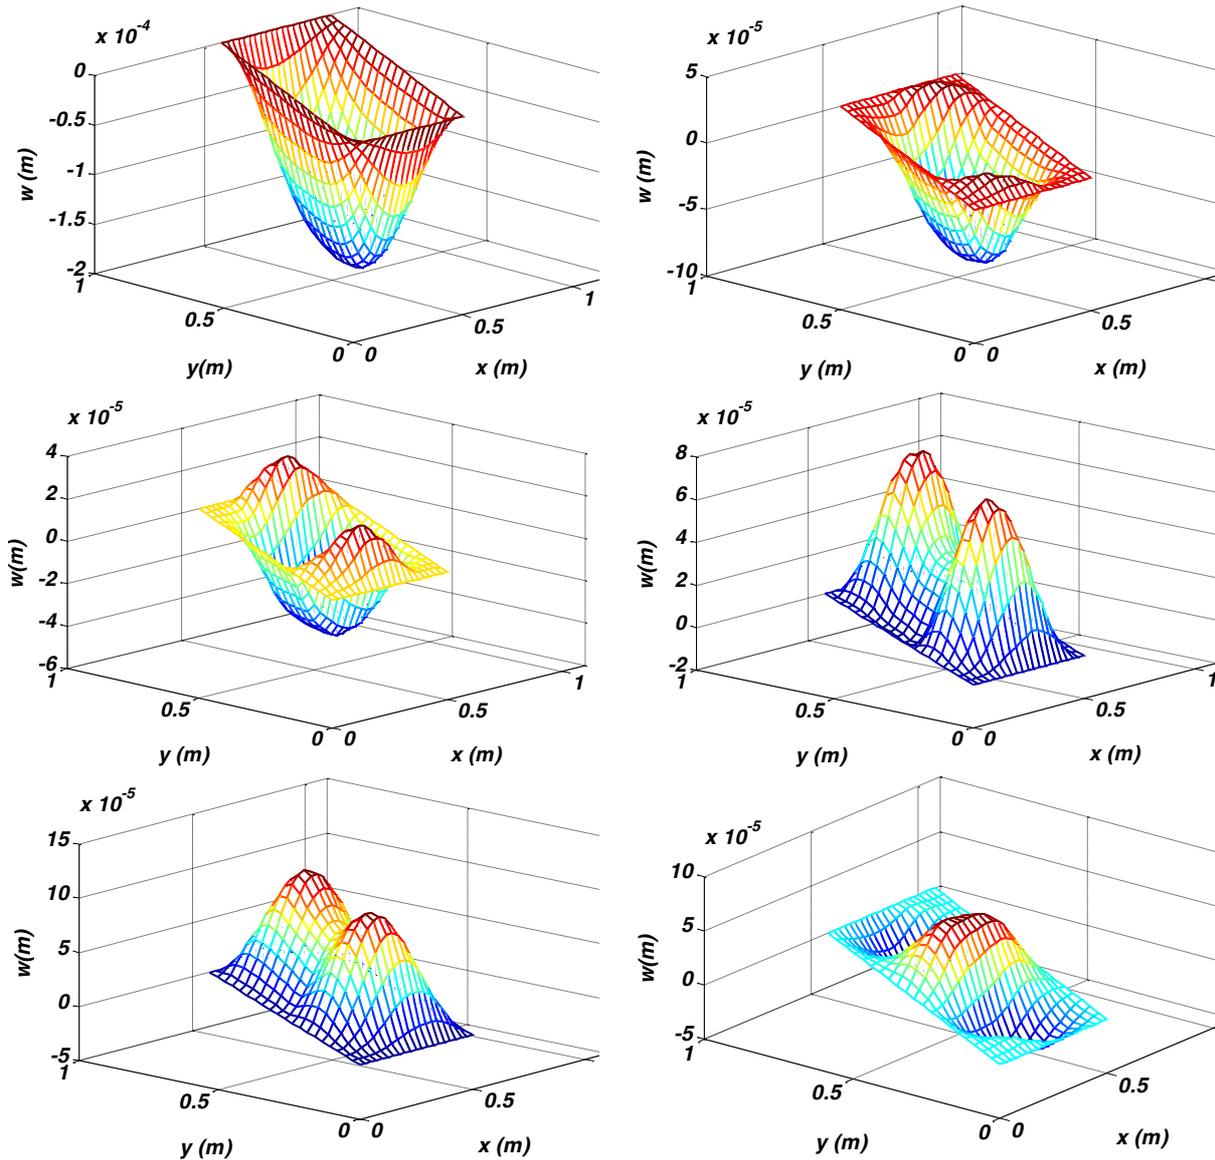

Figure 28 Mid-plane transverse deflection of skew plate for  $n=1$  and  $\varphi = 30^\circ$  after the unloading at  $t=5, 5.061, 5.072, 5.092, 5.103$  and  $5.22$  (ms)

## 5 CONCLUSIONS

In the present paper, static and dynamic analyses of FGM skew plates are obtained based on the three-dimensional theory of elasticity. Graded elements, the principle of minimum energy, and Rayleigh-Ritz energy method are utilized. By applying the three-dimensional graded elements for analysis of the skew plates, discontinuities of the stress distribution that are present in the conventional

FE results, are eliminated. The results are obtained for various material grading index and different skew angles, thus showing the applicability of the present method. In the static analysis, the material properties vary through the thickness direction according to an exponential material gradation and for the dynamic analyses, the effective material properties distribution of the FGM plate was determined using Mori–Tanaka homogenization technique. Results of present formulations are verified by available results of a functionally graded rectangular plate for different boundary conditions and also compared with result of a fully clamped homogenous skew plate that obtained in ANSYS Workbench commercial FE software. The comparison between the results shows good agreement. It is observed that effect of skew angle is considerable on displacement components and stress wave propagation in static and dynamic analyses, respectively. It is because that increasing the skew angle is coupled to the plate stiffening. With certain modifications, the present research can be extended for the analysis of arbitrary quadrilateral plates.
